

Compilation:

- First get the executable 'p2p'.
Command: \$> make
- Open 'n' terminals, where n stands for number of users.
Command: \$> ./p2p <port>
Here, enter the port number of users.

Implementation(For each user):

- A static user_info table is made available to all users in the form of an input file.
- Format for input file:

```
n
<user_1> <ip_1> <port_1>
.
.
<user_n> <ip_n> <port_n>
```

where 'n' stands for number of users.

- A typedef 'peer' is defined which stores name, IPv4 address and a port for each user and a variable prev_conntime for timeout. A global variable **peer *p** is defined.
- First, the user_info from the input file is read and stored in **p**;
- The port number given as command line argument is verified, whether the corresponding user info is present in user_info table or not.
- If present, then a server socket named 'sock_s' is created by setting the paramters accordingly, which listens for incoming connection requests.
- A fd collection 'rd' is initiated and the bits corresponding to STDIN and 'sock_s' are set.
- Then, A timeout value is defined which is to be used by select().
- Now, a while loop runs until user explicitly enters an exit message*.
- In the loop, first, select is called to check if any fds are ready. If the return value is zero(timeout occured), then check whether the user wants to exit. A value is <0 indicates an error in selecting and a positive value indicates that some fds are ready.
- If some fds are ready,

- i) check whether the bit for sock_s is set in the fdset 'temp' i.e, check if the user has some connection to accept. If set, then accept the connection
 - ii) Also, if bit corresponding to STDIN is set in the fdset, i.e, the user is ready to send a msg to some other user.
- After reading the msg to be sent by the user to peer(if any) in the form of <receiver>/<port>, split the input string into receiver and port which can be used to identify the information of corresponding receiver.
 - For this purpose, a typedef 'msg' is defined which contains name, txt corresponding to each message.
 - Now, the port number and ip of the receiver is found out and then checks whether client socket exists or not. If not present, create a socket.
 - send the message to the receiver and the format would be <sender>/<port>.
 - Now, receive the messages from other users, from all sockets available and print them.
 - Timeout is implemented using pthread library, When a user sends a msg and receiver doesn't get reply in TIMEOUT time, then the user closes connection.

Sample Input:

3
p1 127.0.0.1 2000
p2 127.0.0.1 4000
p3 127.0.0.1 6000

Sample Output:

```
chaitanya6575@chaitanya6575-VirtualBox: ~/D...
chaitanya6575@chaitanya6575-VirtualBox:~/Documents/Networks Lab/A8$ ./p2p 6000
User 1: p1, 127.0.0.1, 2000
User 2: p2, 127.0.0.1, 4000
User 3: p3, 127.0.0.1, 6000

Server Running.....
Hi p3, Welcome to p2p!! Enjoy chatting.
p1/hello
Sending msg to 127.0.0.1:2000

=>p1 : I am p1
```

```
chaitanya6575@chaitanya6575-VirtualBox: ~/D...
